-

Question

How does the Field Override work in the Selected Indexes portion of the Duplicate Detection Profiles?

Answer

The override contains the field/subfield in the incoming record to match to the Selected Index in the existing record.

Example

- Selected Index matches on is the 035a
 - Field/Subfield override is added for 019a
 - 019a in the incoming record is matched against the 035a of existing records to check for duplicates.
 - If the incoming record does not contain 019a, no duplicate handling on that index will be performed.
