
Server_f or server_f ssl in web pages configuration?

- **Product:** Aleph
 - **Product Version:** 22, 23
 - **Relevant for Installation Type:** Dedicated-Direct, Direct, Local, Total Care
-

Description

Many web pages contain string "server_f". Do we need to replace "server_f" with "server_f_ssl" in all of them? I found in document "How to configure SSL for Aleph" that only several web files we must change. But in that way, web pages generates mixed -- with some object over HTTP, and some over HTTPS.

Resolution

Please see also explanations in document

["How to set up www_server_conf or specific web pages to use SSL.doc"](#)

Regarding your question:

a. If you want to setup your whole web OPAC to work HTTPS you need to follow the first suggestion in the above

document (E.g. configuration is made in www_server.conf.)

b. If you want only specific web pages to work HTTPS (for example only the login page) then you can follow the second suggestion in the above document.

Indeed when using this method the OPAC is mixed with some pages on HTTP and some on HTTPS.
